# Overview of PDE Solvers

## Mesh-based methods:

- Finite difference method, finite element method, etc.
- High accuracy with numerical convergence
- Curse of dimensionality in approximation:  
 $O(1/\epsilon^d)$  parameters

$$\epsilon = h = O\left(\frac{1}{n}\right) \Leftrightarrow n = O\left(\frac{1}{\epsilon}\right)$$

# Overview of PDE Solvers

Mesh-free methods:

○ Neural network-based methods (dating back to 1990s)

- e.g.,  $\mathcal{D}(u) = f$  in  $\Omega$  and  $\mathcal{B}(u) = g$  on  $\partial\Omega$
- A neural network  $\phi(x; \theta^*)$  is constructed to approximate the solution  $u$  via least square fitting

$$\theta^* = \arg \min_{\theta} \mathcal{L}(\theta) := \arg \min_{\theta} \|\mathcal{D}\phi(x; \theta) - f(x)\|_2^2 + \lambda \|\mathcal{B}\phi(x; \theta) - g(x)\|_2^2$$

or numerically

$$\theta^* = \arg \min_{\theta} \mathcal{L}(\theta) := \arg \min_{\theta} \frac{1}{n} \sum_{i=1}^n |\mathcal{D}\phi(x_i; \theta) - f(x_i)|^2 + \lambda \frac{1}{m} \sum_{j=1}^m |\mathcal{B}\phi(x_j; \theta) - g(x_j)|^2$$

where  $\lambda > 0$  is a hyperparameter

# Overview of PDE Solvers

## Neural networks

- No curse of dimensionality in approximation
  - $O(d^2)$  parameters to achieve arbitrary accuracy, Shen, Y., Zhang, [arXiv:2107.02397](https://arxiv.org/abs/2107.02397)
- Curse of dimensionality in numerical computation
  - Optimal nonlinear approximation with continuous parameter selection, DeVore, Howard, Micchelli, 1989

$$y = h(x; \theta) := T \circ \phi(x) := T \circ h^{(L)} \circ h^{(L-1)} \circ \dots \circ h^{(1)}(x)$$

where

- $h^{(i)}(x) = \sigma(W^{(i)T}x + b^{(i)});$
- $T(x) = V^T x;$
- $\theta = (W^{(1)}, \dots, W^{(L)}, b^{(1)}, \dots, b^{(L)}, V).$

- **Question:** How to obtain a numerical solver scalable in dimension?
- **Idea:** Find an appropriately small function space with stable computation

○ **Question:** What function space is appropriate?

○ **Ideas:**

- Barron space: functions with integral representations (Barron, 1993, E et al. 2019, Du et al. 2021, Xu et al. 2021)

$$\text{e.g. } f(\mathbf{x}) = \int_{\Omega} a \sigma(\mathbf{b}^T \mathbf{x} + c) \rho(da, d\mathbf{b}, dc), \quad \mathbf{x} \in X$$

where  $\rho$  is a probability distribution or more particularly a Fourier representation

$$f(\mathbf{x}) = \int_{\mathbb{R}^d} \hat{f}(\omega) \cos(\omega^T \mathbf{x}) d\omega = \int_{\mathbb{R}^1 \times \mathbb{R}^d} a \cos(\omega^T \mathbf{x}) \rho(da, d\omega)$$

- Ours: functions with **finite expressions**

○ **Question:** Why finite expressions?

○ **Ideas:**

- Simple, intuitive, and interpretable
- Sparse or low-complexity structure of a high-dimensional problem

# Finite Expression Method (FEX)

Liang and Y. [arXiv:2206.10121](https://arxiv.org/abs/2206.10121)

## Motivating Problem:

○ A **structured** high-dimensional Poisson equation

$$-\Delta u = f \quad \text{for } x \in \Omega, \quad u = g \quad \text{for } x \in \partial\Omega$$

with a solution  $u(x) = \frac{1}{2} \sum_{i=1}^d x_i^2$  of low complexity  $O(d)$ , i.e.,  $O(d)$  operators in this expression

## Idea:

○ Find an explicit expression that approximates the solution of a PDE

○ Function space with finite expressions

- **Mathematical expressions:** a combination of symbols with rules to form a valid function, e.g.,  $\sin(2x) + 5$
- **$k$ -finite expression:** a mathematical expression with at most  $k$  operators
- Function space in FEX:  $\mathbb{S}_k$  as the set of  $s$ -finite expressions with  $s \leq k$

# Finite Expression Method (FEX)

Liang and Y. [arXiv:2206.10121](#)

**Advantages:** No curse of dimensionality in approximation

- NN:  $O(d^2)$  parameters to achieve arbitrary accuracy, Shen, Y., Zhang, [arXiv:2107.02397](#)
- NN has finite expressions:
- **Theorem** (Liang and Y. 2022) Suppose the function space is  $\mathcal{S}_k$  generated with operators including  $+$ ,  $-$ ,  $\times$ ,  $/$ ,  $\max\{0, x\}$ ,  $\sin(x)$ , and  $2^x$ . Let  $p \in [1, +\infty)$ . For any  $f$  in the Holder function class  $\mathcal{H}_\mu^\alpha([0, 1]^d)$  and  $\varepsilon > 0$ , there exists a  $k$ -finite expression  $\phi$  in  $\mathcal{S}_k$  such that  $\|f - \phi\|_{L^p} \leq \varepsilon$ , if  $k \geq \mathcal{O}(d^2(\log d + \log \frac{1}{\varepsilon})^2)$ .

# Finite Expression Method (FEX)

Liang and Y. [arXiv:2206.10121](https://arxiv.org/abs/2206.10121)

## Advantages:

- Lessen the curse of dimensionality in numerical computation for structured problems
- To be proved numerically

# Finite Expression Method

Least square based FEX

- e.g.,  $\mathcal{D}(u) = f$  in  $\Omega$  and  $\mathcal{B}(u) = g$  on  $\partial\Omega$
- A mathematical expression  $u^*$  to approximate the PDE solution via

$$u^* = \arg \min_{u \in \mathcal{S}_k} \mathcal{L}(u) := \arg \min_{u \in \mathcal{S}_k} \|\mathcal{D}u - f\|_2^2 + \lambda \|\mathcal{B}u - g\|_2^2$$

- Or numerically

$$u^* = \arg \min_{u \in \mathcal{S}_k} \mathcal{L}(u) := \arg \min_{u \in \mathcal{S}_k} \frac{1}{n} \sum_{i=1}^n |\mathcal{D}u(x_i) - f(x_i)|^2 + \lambda \frac{1}{m} \sum_{j=1}^m |\mathcal{B}u(x_j) - g(x_j)|^2$$

○ Question: how to solve this combinatorial optimization problem?

# Reinforcement Learning for Combinatorial Optimization

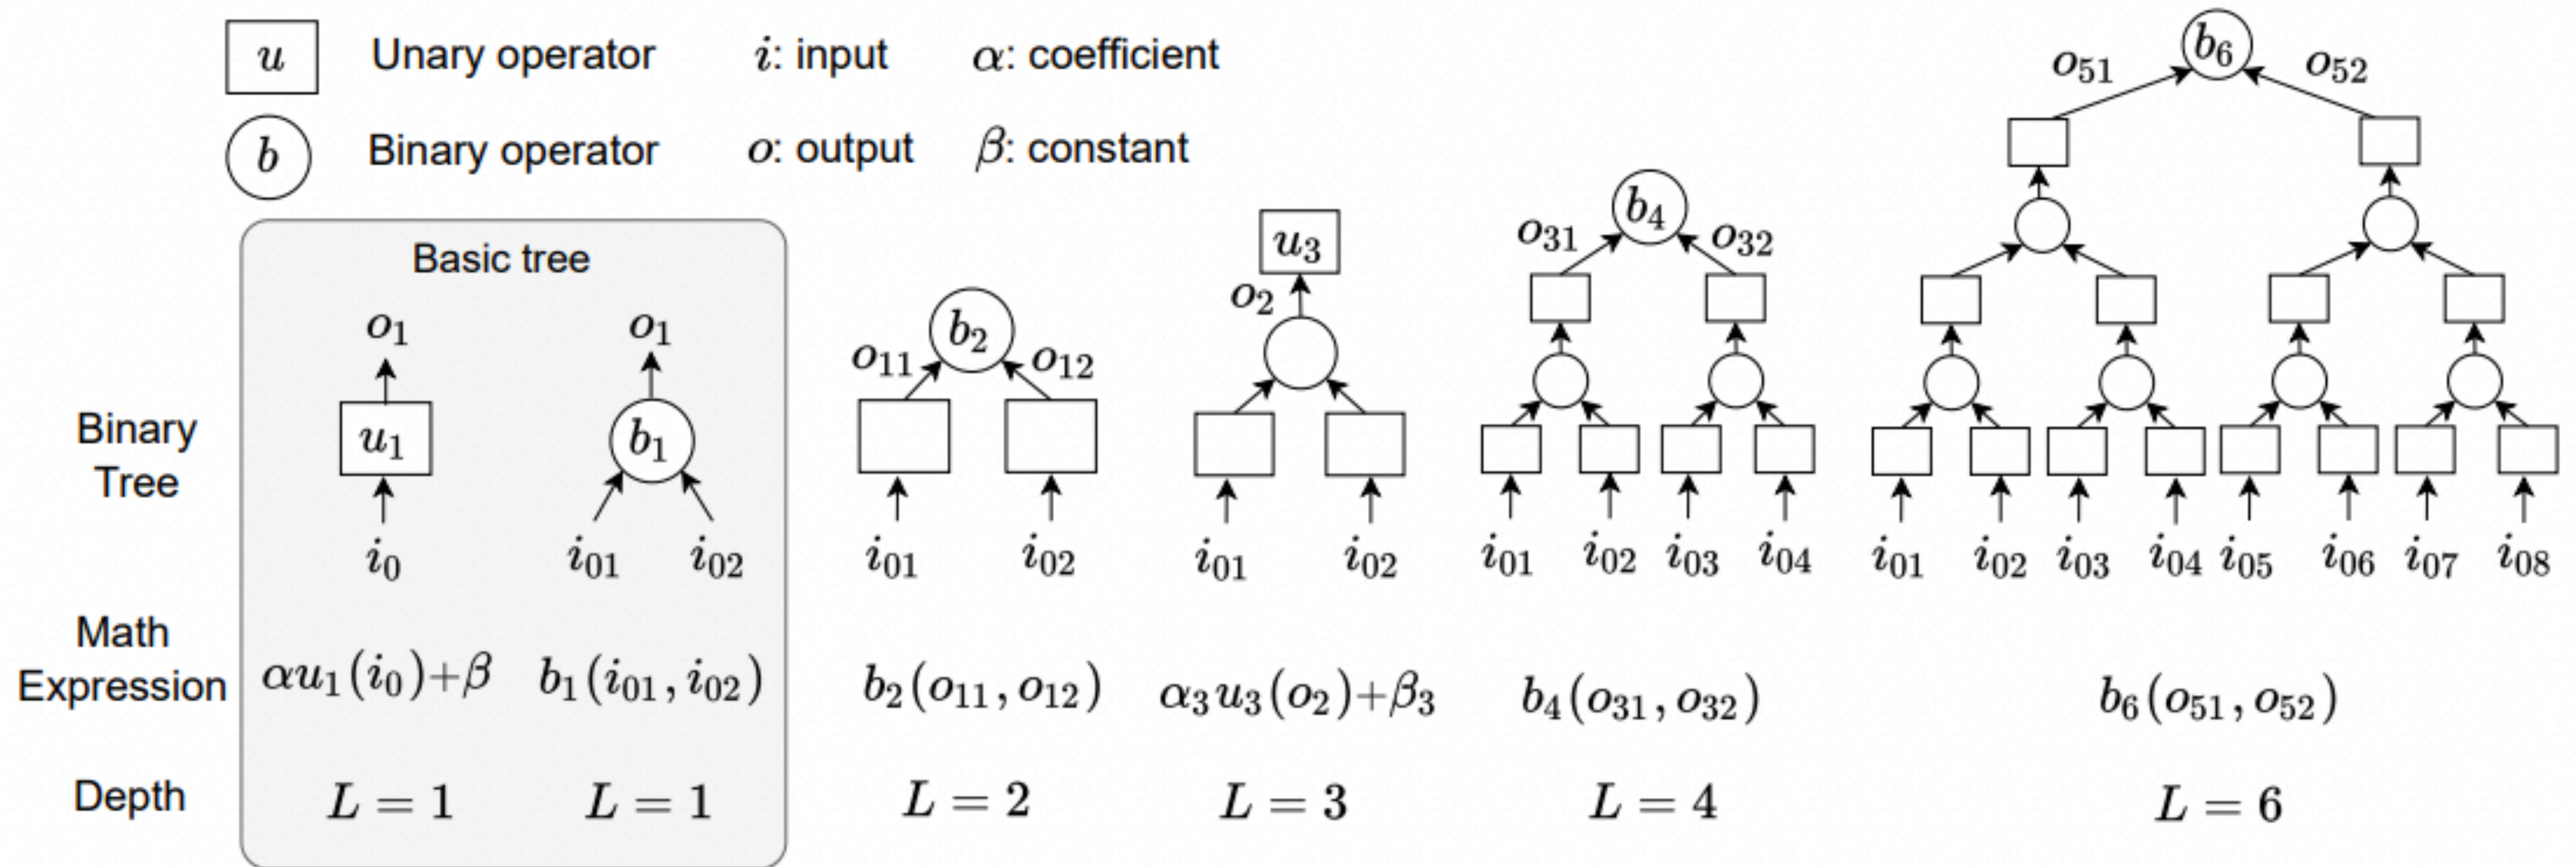

By Richard S. Sutton and Andrew G. Barto.

- **Goal:** Apply reinforcement learning to select mathematical expressions to solve a PDE
- **Ideas:**
  1. Reformulate the sequential (selection, realization, evaluation) procedure as a sequence of (action, state, reward)
  2. Reformulate the decision strategy for selection as the policy to take actions
  3. The PDE regression quality as the reward

# Expression Generation

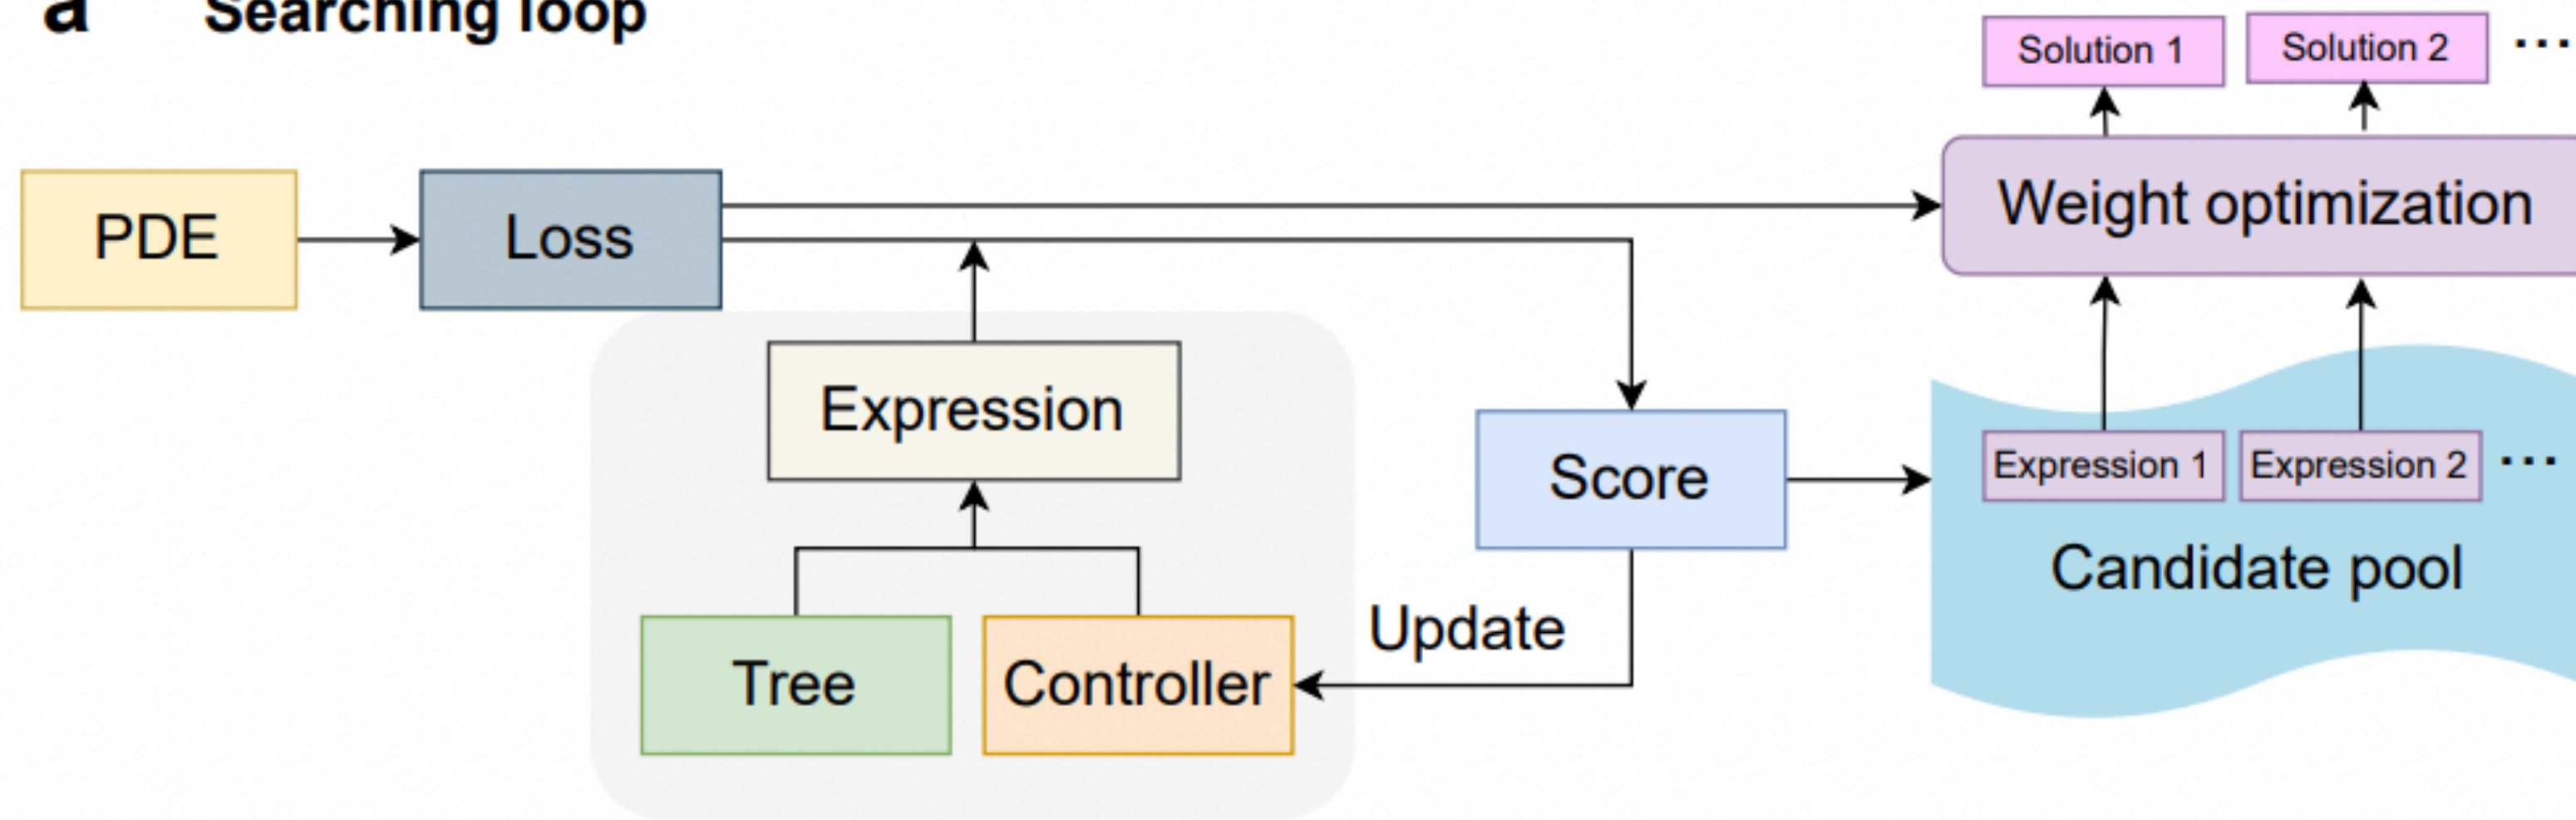

An expression tree as a sequence of node values by using its pre-order traversal, e.g.,  $2 \sin(x) + 3$  and  $x + y$

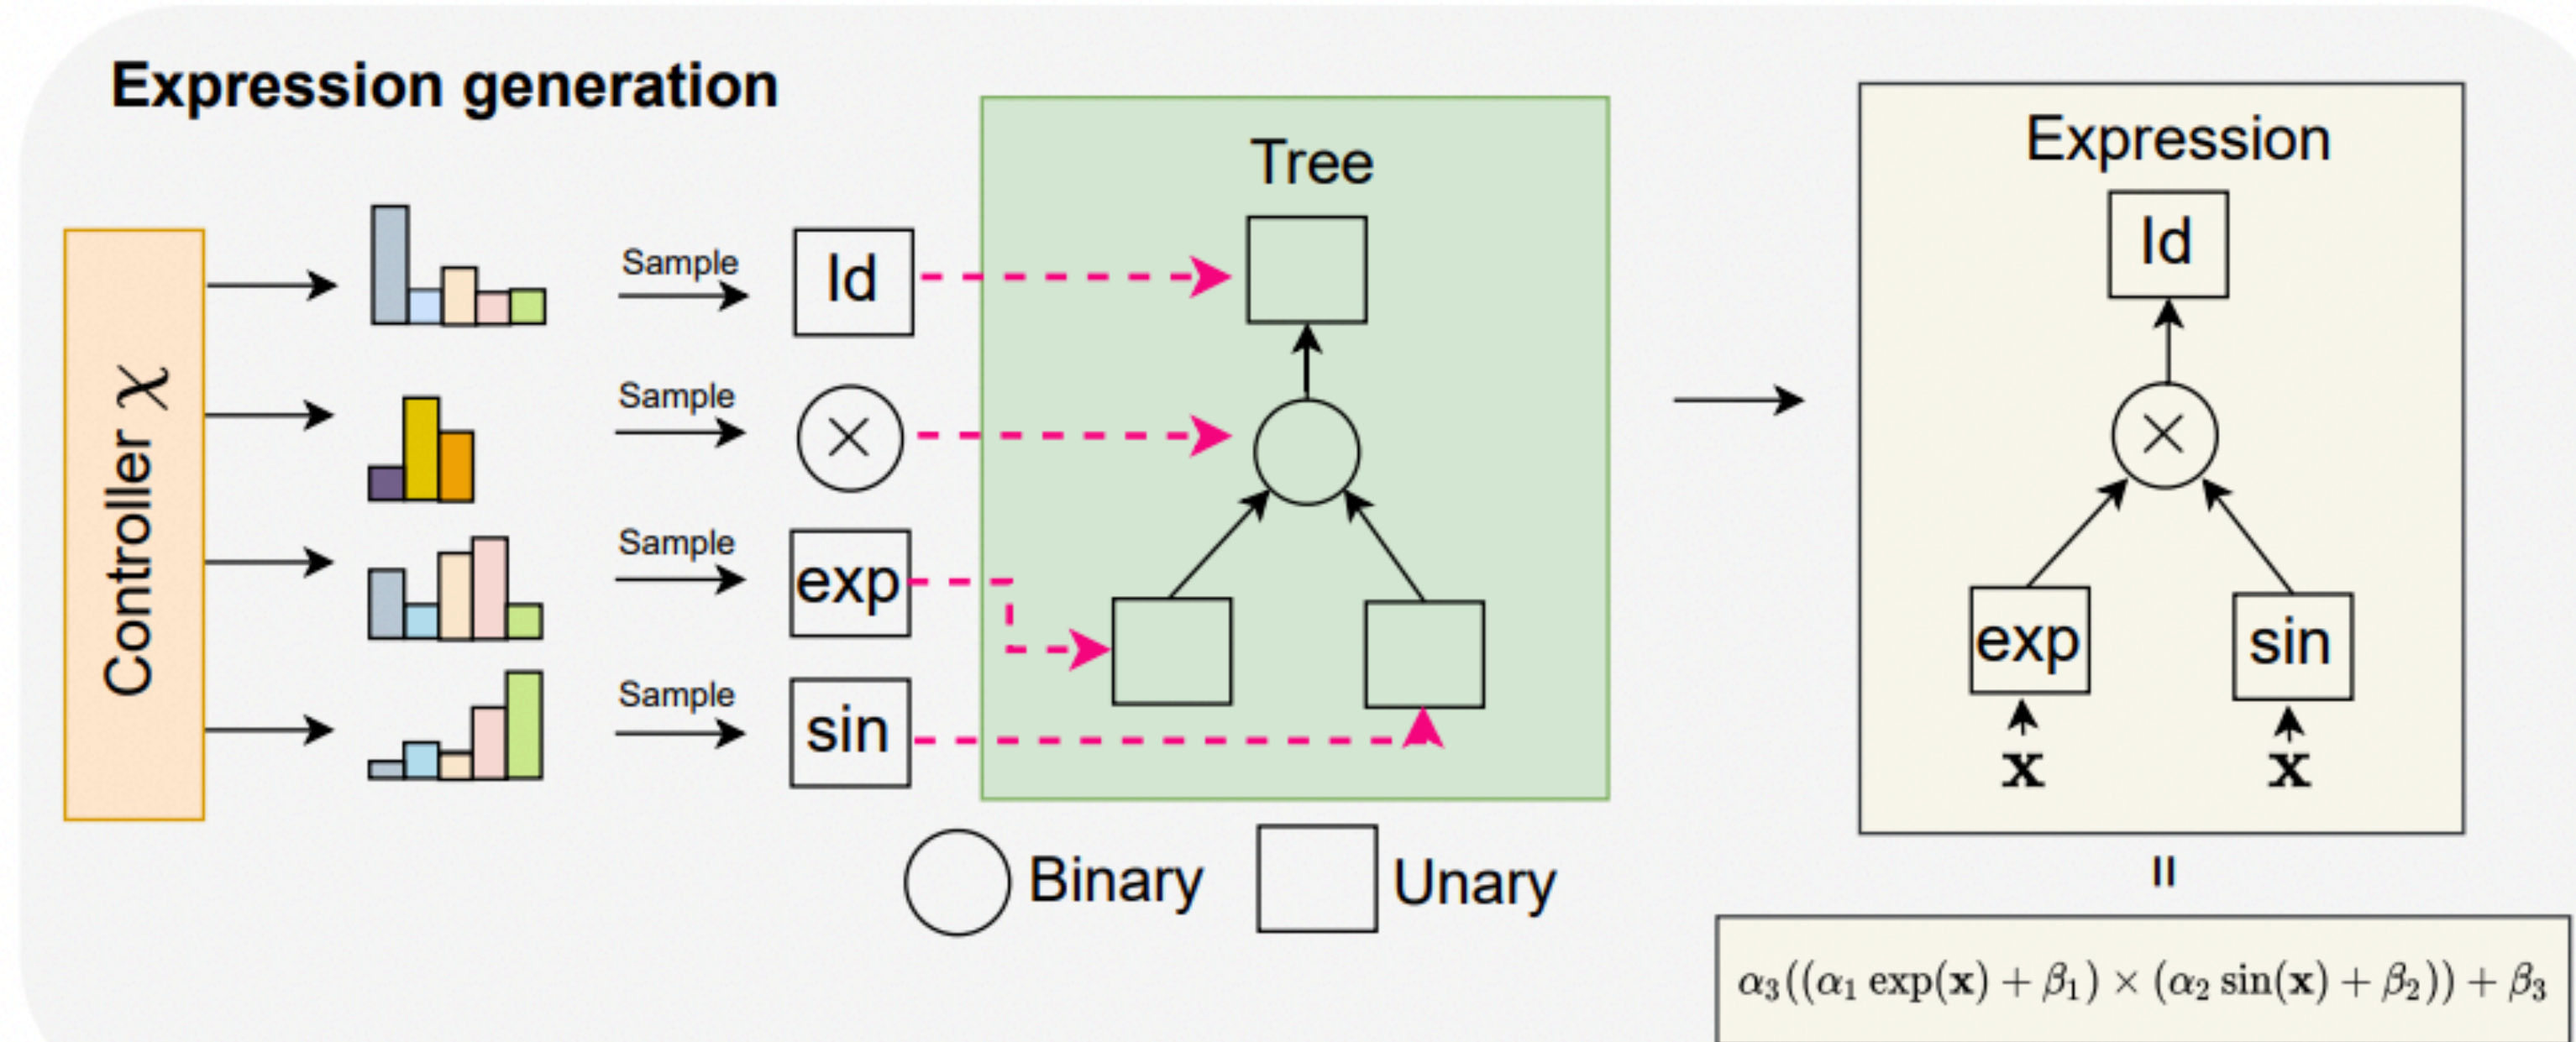

# Computation Flow of FEX

## a Searching loop

## b Expression generation

# Learning to Regress in FEX

- **State** at time  $t$ :  
The expression tree
- **Action** at time  $t$ :  
The operators, variables, and constants drawn from the policy
- **Reward** at time  $t$ :  $R(a_t) = 1/(1 + \mathcal{L}(u))$
- **Policy (controller)**:  $p(a | \theta)$  is the probability specified by a deep neural network

# Numerical Comparison

## ○ NN method:

- Neural networks with a ReLU<sup>2</sup>-activation function
- ResNet with depth 7 and width 50

## ○ FEX method:

- Depth 3 binary tree
- Binary set  $\mathbb{B} = \{ + , - , \times \}$
- Unary set  $\mathbb{U} = \{ 0, 1, \text{Id}, (\cdot)^2, (\cdot)^3, (\cdot)^4, \exp, \sin, \cos \}$

## ○ Fex NN method:

- Apply FEX to obtain an estimated solution structure
- Design NN adaptively with this structure,
- e.g.,  $u(x) = \exp(\text{NN}(x; \theta))$

# Poisson Equation

- Boundary value problem:

$$-\Delta u = f \quad \text{for } x \in \Omega$$

$$u = g \quad \text{for } x \in \partial\Omega$$

- $\Omega = [-1, 1]^d$

- True solution  $u(x) = \frac{1}{2} \sum_{i=1}^d x_i^2$

- Stochastic optimization:

$$\min_{u \in \mathcal{S}_k} \mathcal{L}(u) := \min_{u \in \mathcal{S}_k} \| -\Delta u(x) - f(x) \|_{L^2(\Omega)}^2 + \lambda \| u(x) - g(x) \|_{L^2(\partial\Omega)}^2$$

with Monte Carlo discretization of high-dimensional integrals

# Poisson Equation

# Poisson Equation

Convergence Test:

- True solution  $u(x) = \frac{1}{2} \sum_{i=1}^d x_i^2$
- Binary set  $\mathbb{B} = \{ +, -, \times \}$
- Unary set  $\mathbb{U} = \{ 0, 1, \text{Id}, (\cdot)^3, (\cdot)^4, \text{exp}, \text{sin}, \text{cos} \}$
- No expression tree to exactly represent  $u(x)$

# Linear Conservation Law

- Consider

$$\frac{\pi d}{4} u_t - \sum_{i=1}^d u_{x_i} = 0 \quad \text{for } x = (x_1, \dots, x_d) \in \Omega, t \in [0, 1]$$

$$u(0, x) = \sin\left(\frac{\pi}{4} \sum_{i=1}^d x_i\right) \quad \text{for } x \in \Omega$$

- $T \times \Omega = [0, 1] \times [-1, 1]^d$

- True solution  $u(t, x) = \sin\left(t + \frac{\pi}{4} \sum_{i=1}^d x_i\right)$

- Stochastic optimization:

$$\min_{u \in \mathcal{S}_k} \mathcal{L}(u) := \min_{u \in \mathcal{S}_k} \|u_t - \sum_{i=1}^d u_{x_i}\|_{L^2(T \times \Omega)}^2 + \lambda \|u(0, x) - \sin\left(\frac{\pi}{4} \sum_{i=1}^d x_i\right)\|_{L^2(\Omega)}^2$$

with Monte Carlo discretization of high-dimensional integrals

# Linear Conservation Law

# Nonlinear Schrodinger Equation

- Consider

$$-\Delta u + u^3 + Vu = 0 \quad \text{for } x \in \Omega$$

- $V(x) = -\frac{1}{9} \exp\left(\frac{2}{d} \sum_{i=1}^d \cos x_i\right) + \sum_{i=1}^d \left(\frac{\sin^2 x_i}{d^2} - \frac{\cos x_i}{d}\right)$  for  $x = (x_1, \dots, x_d)$

- $\Omega = [-1, 1]^d$

- True solution  $u(x) = \exp\left(\frac{1}{d} \sum_{j=1}^d \cos(x_j)\right)/3$

- Stochastic optimization:

$$\min_{u \in \mathcal{S}_k} \mathcal{L}(u) := \min_{u \in \mathcal{S}_k} \| -\Delta u + u^3 + Vu \|_{L_2(\Omega)}^2 / \|u\|_{L_2(\Omega)}^3$$

with Monte Carlo discretization of high-dimensional integrals

# Nonlinear Schrodinger Equation

# Eigenvalue Problem

- Consider

$$-\Delta u + w \cdot u = \gamma u, \quad x \in \Omega$$

$$u = 0, \quad x \in \partial\Omega$$

- $\Omega = [-3,3]^d$  and  $w = \|x\|_2^2$

- The smallest eigenfunction is  $u(x) = \exp(-2\|x\|_2^2)$

- Stochastic optimization (DeepRitz, Weinan E and Bing Yu, 2017):

$$\min_{u \in \mathcal{S}_k} \mathcal{L}(u) := \min_{u \in \mathcal{S}_k} \mathcal{F}(u) + \lambda_1 \int_{\partial\Omega} u^2 dx + \lambda_2 \left( \int_{\Omega} u^2 dx - 1 \right)^2$$

with Rayleigh quotient

$$\mathcal{F}(u) = \frac{\int_{\Omega} \|\nabla u\|_2^2 dx + \int_{\Omega} w \cdot u^2 dx}{\int_{\Omega} u^2 dx}$$

# Eigenvalue Problem

# Finite Expression Method

## Conclusion

- **Theory:**  $O(d^2)$  finite expressions approximate  $d$ -dimensional continuous functions to arbitrary accuracy
- **Algorithm:** reinforcement learning solve combinatorial optimization to identify expressions to solve PDEs
- **Advantage:** PDE solver scalable in dimension with high accuracy
- Preprint: Liang and Y. [arXiv:2206.10121](https://arxiv.org/abs/2206.10121)
